## 1978 ITTC Performance Prediction Method

### 1. PURPOSE OF PROCEDURE

The procedure gives a general description of an analytical method to predict delivered power and rate of revolutions for single and twin screw ships from model test results.

### 2. DESCRIPTION OF PROCEDURE

#### 2.1 Introduction

The method requires respective results of a resistance test, a self propulsion test and the characteristics of the model propeller used during the self propulsion test,

The method generally is based on thrust identity which is recommended to be used to predict the performance of a ship. It is supposed that the thrust deduction factor and the relative rotative efficiency calculated for the model remain the same for the full scale ship whereas on all other coefficients corrections for scale effects are applied.

In some special cases torque identity (power identity) may be used, see section 2.4.4.

#### 2.2 Definition of Variables

$C_A$  Correlation allowance  
 $C_{AA}$  Air resistance coefficient  
 $C_{APP}$  Appendage resistance coefficient  
 $C_D$  Drag coefficient  
 $C_{DA}$  Air drag coefficient of the ship above the water line  
 $C_F$  Frictional resistance coefficient

$C_{FC}$  Frictional resistance coefficient at the temperature of the self propulsion test  
 $C_{NP}$  Trial correction for propeller rate of revolution at power identity  
 $C_P$  Trial correction for delivered power  
 $C_N$  Trial correction for propeller rate of revolution at speed identity  
 $C_W$  Wave resistance coefficient  
 $C_T$  Total resistance coefficient  
 $D$  Propeller diameter  
 $F_D$  Skin friction correction in self propulsion test  
 $J$  Propeller advance coefficient  
 $J_T$  Propeller advance coefficient achieved by thrust identity  
 $J_Q$  Propeller advance coefficient achieved by torque identity  
 $K_T$  Propeller thrust coefficient  
 $K_{TQ}$  Thrust coefficient achieved by torque identity  
 $K_Q$  Propeller torque coefficient  
 $K_{QT}$  Torque coefficient achieved by thrust identity  
 $k$  Form factor  
 $k_P$  Propeller blade roughness  
 $k_S$  roughness of hull surface  
 $N_P$  Number of propellers  
 $n$  Propeller rate of revolution  
 $n_T$  Propeller rate of revolution, corrected using correlation factor  
 $P$  Propeller pitch  
 $P_D, P_P$  Delivered Power, propeller power  
 $P_{DT}$  Delivered Power, corrected using correlation factor  
 $P_E, P_R$  Effective power, resistance power  
 $Q$  Torque  
 $R_C$  Resistance corrected for temperature differences between resistance and self propulsion test  
 $Re$  Reynolds number

$R_T$	Total resistance
$S$	Wetted surface area
$S_{BK}$	Wetted surface of bilge keels
$T$	Propeller thrust
$t$	Thrust deduction factor
$V$	Speed
$V_A$	Advance speed of propeller
$w$	Taylor wake fraction in general
$w_Q$	Taylor wake fraction, torque identity
$w_R$	Effect of the rudder(s) on the wake fraction
$w_T$	Taylor wake fraction, thrust identity
$Z$	Number of propeller blades
$\beta$	Appendage scale effect factor
$\Delta C_F$	Roughness allowance
$\Delta C_{FC}$	Individual correction term for roughness allowance
$\Delta w_C$	Individual correction term for wake
$\eta_D$	Propulsive efficiency or quasi-propulsive coefficient
$\eta_H$	Hull efficiency
$\eta_0$	Propeller open water efficiency
$\eta_R$	Relative rotative efficiency
$\rho$	Water density in general
$R_0$	Full scale resistance without overload(N)
$F_x$	External tow force (N)
$F_D$	Skin friction correction force (N)
$A$	Scale factor (-)
$C_{TAdd}$	Added resistance Coefficient (-)
$\Delta R$	Added resistance (N)
$\Delta V$	Added velocity (m/s)
$\Delta n$	Added rpm
$\zeta_n$	Load variation coefficient of the shaft revolution speed
$\zeta_v$	Load variation coefficient of the ship speed
$\zeta_P$	Load variation coefficient of the delivered power

Subscript “<sub>M</sub>” signifies the model

Subscript “<sub>s</sub>” signifies the full scale ship

### 2.3 Analysis of the Model Test Results

The calculation of the residual resistance coefficient  $C_R$  from the model resistance test results is found in the procedure for resistance test (7.5-02-02-01).

Thrust  $T_M$ , and torque  $Q_M$ , measured in the self-propulsion tests are expressed in the non-dimensional forms as in the procedure for propulsion test (7.5-02-03-01.1).

$$K_{TM} = \frac{T_M}{\rho_M D_M^4 n_M^2} \quad \text{and} \quad K_{QM} = \frac{Q_M}{\rho_M D_M^5 n_M^2}$$

Using thrust identity with  $K_{TM}$  as input data,  $J_{TM}$  and  $K_{QTM}$  are read off from the model propeller open water diagram, and the wake fraction

$$w_{TM} = 1 - \frac{J_{TM} D_M n_M}{V_M}$$

and the relative rotative efficiency

$$\eta_R = \frac{K_{QTM}}{K_{QM}}$$

are calculated.  $V_M$  is model speed.

Using torque identity with  $K_{QM}$  as input data,  $J_{QM}$  and  $K_{TQM}$  is read off from the model propeller open water diagram, and the wake fraction

$$w_{QM} = 1 - \frac{J_{QM} D_M n_M}{V_M}$$

and the relative rotative efficiency

$$\eta_R = \frac{K_{TQM}}{K_{TM}}$$

are calculated.  $V_M$  is model speed.

The thrust deduction is obtained from

$$t = \frac{T_M + F_D - R_C}{T_M}$$

where  $F_D$  is the towing force actually applied in the propulsion test.  $R_C$  is the resistance corrected for differences in temperature between resistance and self-propulsion tests:

$$R_C = \frac{(1+k)C_{FMC} + C_W}{(1+k)C_{FM} + C_W} R_{TM}$$

where  $C_{FMC}$  is the frictional resistance coefficient at the temperature of the self-propulsion test.

## 2.4 Full Scale Predictions

### 2.4.1 Total resistance of ship

The total resistance coefficient of a ship without bilge keels is

$$C_{TS} = (1+k)C_{FS} + \Delta C_F + C_A + C_W + C_{AAS}$$

where

- $k$  is the form factor determined from the resistance test, see ITTC standard procedure 7.5-02-02-01.
- $C_{FS}$  is the frictional resistance coefficient of the ship according to the ITTC-1957 model-ship correlation line
- $C_W$  is the wave resistance coefficient calculated from the total and frictional resistance coefficients of the model in the resistance tests:

$$C_W = C_{TM} - C_{FM}(1+k)$$

The form factor  $k$  and the total resistance coefficient for the model  $C_{TM}$  are determined as described in the ITTC standard procedure 7.5-02-02-01.

The correlation factor for the calculation of the resistance has been separated from the roughness allowance. The roughness allowance  $\Delta C_F$  per definition describes the effect of the roughness of the hull on the resistance. The correlation factor  $C_A$  is supposed to allow for all effects not covered by the prediction method, mainly uncertainties of the tests and the prediction method itself and the assumptions made for the prediction method. The separation of  $\Delta C_F$  from  $C_A$  was proposed by the Performance Prediction Committee of the 19<sup>th</sup> ITTC. This is essential to allow for the effects of newly developed hull coating systems.

The 19<sup>th</sup> ITTC also proposed a modified formula for  $C_A$  that excludes roughness allowance, which is now given in this procedure.

- $\Delta C_F$  is the roughness allowance

$$\Delta C_F = 0.044 \left[ \left( \frac{k_S}{L_{WL}} \right)^{\frac{1}{3}} - 10 \cdot Re^{-\frac{1}{3}} \right] + 0.000125$$

where  $k_S$  indicates the roughness of hull surface. When there is no measured data, the standard value of  $k_S = 150 \cdot 10^{-6}$  m can be used. For modern coating different value will have to be considered.

- $C_A$  is the correlation allowance

$C_A$  is determined from comparison of model and full scale trial results. When using the roughness allowance as above, the 19<sup>th</sup> ITTC recommended using

$$C_A = (5.68 - 0.6 \log Re) \times 10^{-3}$$

It is recommended that each institution maintains their own model-full scale correlation. See section 2.4.4 for a further discussion on correlation.

- $C_{AAS}$  is the air resistance coefficient in full scale

$$C_{AAS} = C_{DA} \frac{\rho_A \cdot A_{VS}}{\rho_S \cdot S_S}$$

where,  $A_{VS}$  is the projected area of the ship above the water line to the transverse plane,  $S_S$  is the wetted surface area of the ship,  $\rho_A$  is the air density, and  $C_{DA}$  is the air drag coefficient of the ship above the water line.  $C_{DA}$  can be determined by wind tunnel model tests or calculations. Values of  $C_{DA}$  are typically in the range 0.5-1.0, where 0.8 can be used as a default value.

If the ship is fitted with bilge keels of modest size, the total resistance is estimated as follows:

$$C_{TS} = \frac{S_S + S_{BK}}{S_S} [(1+k)C_{FS} + \Delta C_F + C_A] + C_R + C_{AAS}$$

where  $S_{BK}$  is the wetted surface area of the bilge keels.

When the model appendage resistance is separated from the total model resistance, as described as an option in the ITTC Standard Procedure 7.5-02-02-01, the full scale appendage resistance needs to be added, and the formula for total resistance (with bilge keels) becomes:

$$C_{TS} = \frac{S_S + S_{BK}}{S_S} [(1+k)C_{FS} + \Delta C_F + C_A] + C_W + C_{AAS} + C_{APPS}$$

There is not only one recommended method of scaling appendage resistance to full scale. The following alternative methods are well established:

- 1) Scaling using a fixed fraction:

$$C_{APPS} = (1-\beta)C_{APPM}$$

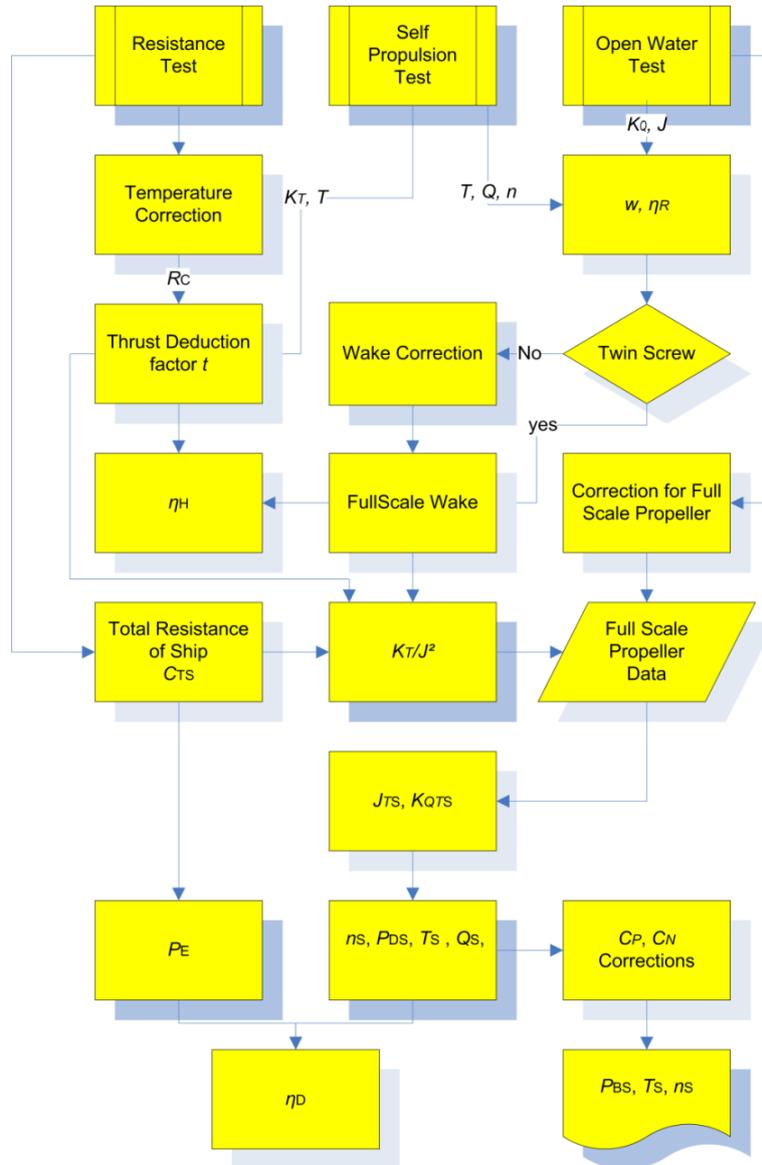

where  $(1-\beta)$  is a constant in the range 0.6-1.0.

- 2) Calculating the drag of each appendage separately, using local Reynolds number and form factor.

$$C_{APPS} = \sum (1-w_i)^2 (1+k_i) C_{FSi} \frac{S_i}{S_S}$$

$$Re = \frac{V \left( \frac{S_{APP}}{2} \right)^{\frac{1}{2}}}{\nu} \quad \text{or} \quad Re = \frac{VL}{\nu}$$

where index  $i$  refers to the number of the individual appendices.  $w_i$  is the wake fraction at the position of appendage  $i$ .  $k_i$  is the form factor of appendage  $i$ .  $C_{FSi}$  is the frictional resistance coefficient of appendage  $i$ , and  $S_i$  is the wetted surface area of appendage  $i$ . Note that the method is not scaling the model appendage drag, but calculating the full scale appendage drag. The model appendage drag, if known from model tests, can be used for the determination of e.g. the wake fractions  $w_i$ . Values of the form factor  $k_i$  can be found from published data for generic shapes, see for instance Hoerner (1965) or Kirkman and Klöetsli (1980).  $L$  is the characteristic length of appendage.

#### 2.4.2 Scale effect corrections for propeller characteristics

The characteristics of the full-scale propeller are calculated from the model characteristics as follows:

$$K_{TS} = K_{TM} - \Delta K_T$$

$$K_{QS} = K_{QM} - \Delta K_Q$$

$$\Delta K_T = -\Delta C_D \cdot 0.3 \cdot \frac{P}{D} \cdot \frac{c \cdot Z}{D}$$

$$\Delta K_Q = \Delta C_D \cdot 0.25 \cdot \frac{c \cdot Z}{D}$$

The difference in drag coefficient  $\Delta C_D$  is

$$\Delta C_D = C_{DM} - C_{DS}$$

where

where

$$C_{DM} = 2 \left( 1 + 2 \frac{t}{c} \right) \left[ \frac{0.044}{(Re_{c0})^{\frac{1}{6}}} - \frac{5}{(Re_{c0})^{\frac{2}{3}}} \right]$$

and

$$C_{DS} = 2 \left( 1 + 2 \frac{t}{c} \right) \left( 1.89 + 1.62 \cdot \log \frac{c}{k_P} \right)^{-2.5}$$

In the formulae listed above  $c$  is the chord length,  $t$  is the maximum thickness,  $P/D$  is the pitch ratio and  $Re_{c0}$  is the local Reynolds number with Kempf's definition at the open-water test. They are defined for the representative blade section, such as at  $r/R=0.75$ .  $k_P$  denotes the blade roughness, the standard value of which is set  $k_P=30 \cdot 10^{-6}$  m.  $Re_{c0}$  must not be lower than  $2 \cdot 10^5$ .

#### 2.4.3 Full scale wake and operating condition of propeller

The full-scale wake is calculated by the following formula using the model wake fraction  $w_{TM}$ , and the thrust deduction fraction  $t$  obtained as the analysed results of self-propulsion test:

$$w_{TS} = (t + w_R) + (w_{TM} - t - w_R) \frac{(1+k)C_{FS} + \Delta C_F}{(1+k)C_{FM}}$$

where  $w_R$  stands for the effect of rudder on the wake fraction. If there is no estimate for  $w_R$ , the standard value of 0.04 can be used.

If the estimated  $w_{TS}$  is greater than  $w_{TM}$ ,  $w_{TS}$  should be set as  $w_{TM}$ .

The wake scale effect of twin screw ships with open sterns is usually small, and for such ships it is common to assume  $w_{TS} = w_{TM}$ .

For twin skeg-like stern shapes a wake correction is recommended. A correction like the one used for single screw ships may be used.

The load of the full-scale propeller is obtained from

$$\frac{K_T}{J^2} = \frac{1}{N_P} \cdot \frac{S_S}{2D_S^2} \cdot \frac{C_{TS}}{(1-t) \cdot (1-w_{TS})^2}$$

where  $N_P$  is the number of propellers.

With this  $K_T / J^2$  as input value the full scale advance coefficient  $J_{TS}$  and the torque coefficient  $K_{QTS}$  are read off from the full scale propeller characteristics and the following quantities are calculated.

- the rate of revolutions:

$$n_S = \frac{(1-w_{TS}) \cdot V_S}{J_{TS} \cdot D_S} \quad (\text{r/s})$$

- the delivered power of each propeller:

$$P_{DS} = 2\pi\rho_S D_S^5 n_S^3 \frac{K_{QTS}}{\eta_R} \cdot 10^{-3} \quad (\text{kW})$$

- the thrust of each propeller:

$$T_S = \left( \frac{K_T}{J^2} \right) \cdot J_{TS}^2 \rho_S D_S^4 n_S^2 \quad (\text{N})$$

- the torque of each propeller:

$$Q_S = \frac{K_{QTS}}{\eta_R} \cdot \rho_S D_S^5 n_S^2 \quad (\text{Nm})$$

- the effective power:

$$P_E = C_{TS} \cdot \frac{1}{2} \rho_S V_S^3 S_S \cdot 10^{-3} \quad (\text{kW})$$

- the quasi propulsive efficiency:

$$\eta_D = \frac{P_E}{N_P \cdot P_{DS}}$$

- the hull efficiency:

$$\eta_H = \frac{1-t}{1-w_{TS}}$$

#### 2.4.4 Model ship correlation factor

The model-ship correlation factor should be based on systematic comparison between full scale trial results and predictions from model scale tests. Thus, it is a correction for any systematic errors in model test and powering prediction procedures, including any facility bias.

In the following, several different alternative concepts of correlation factors are presented as suggestions. It is left to each member organisations to derive their own values of the correlation factor(s), taking into account also the actual value used for  $C_A$ .

##### (1) Prediction of full scale rates of revolutions and delivered power by use of the $C_P - C_N$ correction factors

Using  $C_P$  and  $C_N$  the finally predicted trial data will be calculated from

$$n_T = C_N \cdot n_S \quad (\text{r/s})$$

for the rates of revolutions and

$$P_{DT} = C_P \cdot P_{DS} \quad (\text{kW})$$

for the delivered power.

##### (2) Prediction of full scale rates of revolutions and delivered power by use of $\Delta C_{FC} - \Delta w_C$ corrections

In such a case the finally trial predicted trial data are calculated as follows:

$$\frac{K_T}{J^2} = \frac{1}{N_P} \cdot \frac{S_S}{2D_S^2} \cdot \frac{C_{TS} + \Delta C_{FC}}{(1-t) \cdot (1-w_{TS} + \Delta w_C)^2}$$

With this  $K_T/J^2$  as input value,  $J_{TS}$  and  $K_{QTS}$  are read off from the full scale propeller characteristics and the following is calculated:

$$n_T = \frac{(1-w_{TS} + \Delta w_C) \cdot V_S}{J_{TS} \cdot D_S} \quad (\text{r/s})$$

$$P_{DT} = 2\pi\rho_S D_S^5 n_T^3 \frac{K_{QTS}}{\eta_R} \cdot 10^{-3} \quad (\text{kW})$$

##### (3) Prediction of full scale rates of revolutions and delivered power by use of a $C_{NP}$ correction

For prediction with emphasis on stator fins and rudder effects, it is sometimes recommended to use power identity for the prediction of full scale rates of revolution.

At the point of  $K_T(J)$ -Identity the condition is reached where the ratio between the propeller induced velocity and the entrance velocity is the same for the model and the full scale ship. Ignoring the small scale effect  $\Delta K_T$  on the thrust coefficient  $K_T$  it follows that J-identity correspond to  $K_T$ - and  $C_T$ -identity. As a consequence it follows that for this condition the axial flow field in the vicinity of the propeller is on average correctly simulated in the model experiment. Also the axial flow of the propeller slip stream is on average correctly simulated. Due to the scale effects on the propeller blade friction, which affect primarily the torque, the point of  $K_Q$ -identity (power identity) represents a slightly less heavily loaded propeller than at  $J$ -,  $K_T$ - and  $C_T$ -identity. At the power identity the average rotation in the slipstream corresponds to

that of the actual ship and this condition is regarded as important if tests on stator fins and/or rudders are to be done correctly.

In this case, the shaft rate of revolutions is predicted on the basis of power identity as follows:

$$\left(\frac{K_Q}{J^3}\right)_T = \frac{1000 \cdot C_P \cdot P_{DS}}{2\pi\rho_S D_S^2 V_S^3 (1-w_{TS})^3}$$

$$\frac{K_{Q0}}{J^3} = \left(\frac{K_Q}{J^3}\right)_T \cdot \eta_{RM}$$

$$n_S = \frac{(1-w_{TS}) \cdot V_S}{J_{TS} \cdot D_S}$$

$$n_T = C_{NP} \cdot n_S$$

## 2.5 Load Variation Test

### 2.5.1 Purpose of load variation test

Load variation test is conducted to find out the variation of performance such as the efficiency, speed of revolution, propeller torque and thrust according to the variation of load on ship resistance. The self-propulsion test is normally conducted in calm water however the actual ship operates in non-still sea. The load variation test therefore is necessary to be carried out in self-propulsion condition to find out performance dependency on different loading conditions at same speed.

### 2.5.2 Method of load variation test

A load variation test is carried out at the selected draught and at minimum one speed. This speed shall be one of the speeds tested in the normal self-propulsion test. The load variation test includes at least 4 self-propulsion test runs,

each one at a different rate of revolution while keeping the speed constant. The rate of revolutions are to be selected such that

$$\frac{\Delta R}{R_0} \approx [0.1, 0, 0.1, 0.2] \quad (1)$$

Where

$$\Delta R = (F_D - F_X) \lambda^3 \frac{\rho_S}{\rho_M} \quad (2)$$

With reference to the resistance tests and in order to fulfill (1), the target tow force ( $F_X$ ) can be calculated as follows:

$$F_X = F_D - [-0.1, 0, 0.1, 0.2] (R_{TM} - F_D) \quad (3)$$

The “added resistance” in the load variation test has to be accounted for in the post processing. The measured data is processed according to ITTC Recommended Procedure 7.5–02–03–01.4 (1978 ITTC Performance Prediction Method), from section 2.4.3 and onwards, prepared for the standard self-propulsion test at tow force  $F_D$  with one modification. That  $C_{TS}$  is replaced by  $C_{TAdd}$

with

$$C_{TAdd} = C_{TS} + \frac{\Delta R}{\frac{1}{2}\rho_S V_S^2 S_S} \quad (4)$$

### 2.5.3 Dependency of propulsion efficiency with resistance increase

The fraction between the propulsion efficiency considering the load variation effect  $\eta_{DM}$  and that in ideal condition  $\eta_D$  is plotted against the fraction between the resistance increase  $\Delta R$  and resistance in ideal condition  $R_0$ . Figure 2 shows an example. The variable  $\zeta_P$  is the slope of the linear curve ideally going through {0, 1}

and fitted to the data points with least square method.

$$\frac{\eta_{DM}}{\eta_D} = \xi_P \frac{\Delta R}{R_0} + 1 \quad (5)$$

#### 2.5.4 Dependency of shaft rate with power increase

Similarly, the effect on shaft rate  $\Delta n/n$  (the fraction between the deviation of shaft rate due to load variation effect  $\Delta n$  and the shaft rate in ideal condition  $n$ ) is plotted against  $\Delta P/P_{D0}$  (the fraction between power increase  $\Delta P$  and the power in ideal condition  $P_D$ ). The variable  $\xi_n$  is the slope of the linear curve ideally going through  $\{0, 0\}$  and fitted to the data points with least square method. Figure 3 gives an example.

$$\frac{\Delta n}{n} = \xi_N \frac{\Delta P_D}{P_{D0}} \quad (6)$$

#### 2.5.5 Dependency of shaft rate with speed change

The dependency of shaft rate with speed is derived through the following steps:  
The shaft rate  $n$  in ideal condition is plotted against the resistance  $R_0 + \Delta R$  ( $\Delta R = 0$ ) for a number of speeds in the same graph (in Figure 4). The shaft rate  $n$  considering the load variation effect is plotted against the resistance  $R_0 + \Delta R$  ( $\Delta R \neq 0$ ) for the speed closest to the predicted EEDI (Dashed line in Figure 4). In addition, the linear curve going through  $\{R_0, n\}$  and fitted to the data points  $\{R_0 + \Delta R, n\}$  is obtained with least square method. Lines going through the point  $\{R_0, n\}$  for each speed and parallel to the linear curve obtained above are plotted. A vertical line going through the resistance in ideal condition for the speed closest to the predicted EEDI speed is plotted in the graph (in Figure 4) From the intersections of lines (square  $\square$ ), the shaft

rate for the corresponding speed of the each line can be obtained.

For each of the intersection points, compute  $\Delta V/V$  relative to the speeds which is closest to the predicted EEDI speed. For each of the intersection points, compute  $\Delta n/n$  relative to the  $n$ -values which is closest to the predicted EEDI speed. These points in a  $\Delta n/n$  over  $\Delta V/V$  graph (Figure 5) are plotted. This gives the rpm dependency of speed. The slope of the  $\Delta n/n - \Delta V/V$  curve fitted with least square method is  $\xi_v$  (Figure 5).

$$\frac{\Delta n}{n} = \xi_v \frac{\Delta V}{V_s} \quad (7)$$

## 2.6 Documentation

The results from the test should be collated in a report which should contain at least the following information:

- Model Hull Specification:
  - Identification (model number or similar)
  - Draughts and Displacement volume
  - Turbulence stimulation method
  - Model scale
  - Model material
- Main dimensions and hydrostatics (see ITTC Recommended Procedure 7.5-01-01-01 Hull Model).
- Model Propeller Specification
  - Identification (model number or similar)
  - Model Scale
  - Main dimensions and particulars (see ITTC Recommended Procedure 7.5-01-01-01 Propeller/Propulsion unit model)
  - Model material
- Particulars of the towing tank, including length, breadth and water depth
- Test date
- Parametric data for the test:
  - Water temperature in towing tank
  - Water density in towing tank
  - Kinematic viscosity of the water
  - Form factor (even if  $(1+k) = 1.0$  is applicable, this should be stated)
  - Roughness of hull and propeller
  - Water temperature of full-scale
  - Water density of full-scale
- For each speed the following data should be given as a minimum:
  - External tow force
  - Sinkage fore and aft, or sinkage and trim
  - Propeller thrust, torque and rate of revolutions.
  - Correlation allowance  $C_A$
  - Propulsive efficiency
  - Hull efficiency

- Relative rotative efficiency
- Taylor wake fraction
- Thrust deduction factor
- Trial prediction with  $C_P, C_N$
- Ship service prediction (ship speed, rate of revolution, delivered power, Sea Margin)
- Overload factors ( $\xi_N, \xi_P, \xi_V$ )

## 3. VALIDATION

### 3.1 Uncertainty Analysis

Not yet available

### 3.2 Comparison with Full Scale Results

The data that led to 1978 ITTC performance prediction method can be found in the following ITTC proceedings:

1. Proposed Performance Prediction Factors for Single Screw Ocean Going Ships (13<sup>th</sup> 1972 pp.155-180) Empirical Power Prediction Factor (  $1+X$  )
2. Propeller Dynamics Comparative Tests (13<sup>th</sup> 1972 pp.445-446 )
3. Comparative Calculations with the ITTC Trial Prediction Test Programme (14<sup>th</sup> 1975 Vol.3 pp.548-553)
